Polarization of Waves

The electromagnetic waves such as visible light and microwaves consist of orthogonal electric and magnetic field both orthogonal to the propagation direction of the wave. The polarization of the electromagnetic wave is meant to describe the magnitude and the direction of the electric field of the wave. Specifically, the polarization of a radiated wave is defined as "that property of a radiated electromagnetic wave describing the time-varying direction and relative magnitude of the electric field vector; the trace and magnitude of the electric field vector are observed in the direction of light propagation"\textsuperscript{1,2}.

Introduction

The polarization of electromagnetic wave (EMW) is the basic property of the EMW, which is widely used and controlled in Laser\textsuperscript{3,4}, interferometer\textsuperscript{5,6} and photography\textsuperscript{7}. The sketch for the linear polarization (red curves) of EMW is shown in Fig.1 below.
based on the Maxwell equations for EMW, the electric field can be split into orthogonal x-component $E_x$ and y-component $E_y$:

$$
\varepsilon_x = \bar{a}_x E_x \cos (\omega t + \phi_x)
$$

$$
\varepsilon_y = \bar{a}_y E_y \cos (\omega t + \phi_y)
$$

where $E_x$ is the magnitude of the electric field in x-direction, $E_y$ is the magnitude of the electric field in x-direction, $\phi_x$ is the phase of the electric field in x-direction, $\phi_y$ is the phase of the electric field in y-direction and omega is the frequency of the EMW. The three major polarization state are defined based on the differences in phase and magnitude of x-direction and y-direction EMW.

**Linear Polarization**

Assume $E_y$ in the mathematical expression for the electric field equals to zero, which gives the definition of electric field as:

$$
\varepsilon_x = \bar{a}_x E_x \cos (\omega t + \phi_x)
$$

$$
\varepsilon_y = 0
$$

The electric field on certain propagation position will oscillate only on the x-axis with the angular frequency of omega, which is shown as below:
Fig. 2 x-axis linear polarization

Thus, the similar polarization of electric field on only a specific straight direction is defined as linear polarization. On the other hand, Assume $E_y$ equals to zero, which gives the electric field as:

$$\varepsilon_x = 0$$
$$\varepsilon_y = \overline{\alpha}_y E_x \cos (\omega t + \varphi_y)$$

The electric field only oscillate on the $y$-axis with the angular frequency of omega, which is shown in Fig.3:

Fig. 3 y-axis linear polarization

Generally, with $x$-direction oscillation and $y$-direction oscillation share the same phase, the linear polarization field pattern can be express as:

$$\varepsilon_x = \overline{\alpha}_x E_x \cos (\omega t + \psi)$$
$$\varepsilon_y = \overline{\alpha}_y E_y \cos (\omega t + \psi)$$

the angle of the linear oscillation towards the $x$-axis is calculated as:

$$\theta = \arctan \left( \frac{E_y}{E_x} \right)$$
The polarization sketch is shown in Fig. 4:

![Circular Polarization](https://eng.libretexts.org/Bookshelves/Materials_Science/Supplemental_Modules_(Materials_Science)/Optical_Properties/Polarization/Circular_Polarization.pdf)

**Circular Polarization**

The circular polarization state is a special polarization state of elliptical polarization state, which satisfies the following conditions: 1) The field must have two orthogonal polarized components (such as x-direction and y-direction). 2) The two components must have the same magnitude ($E_x = E_y$). 3) The two components must have a time-phase difference of multiples of 90 degrees. Thus the field pattern can be written as:

$$
\varepsilon_x = a_x E_0 \cos(\omega t)
$$

$$
\varepsilon_y = a_y E_0 \cos(\omega t + \frac{n\pi}{2}) \quad n \text{ is odd number}
$$

And the polarization pattern can be drawn as Fig.4 and Fig.5:
Elliptical Polarization

The elliptical polarization is the general definition of the EMW polarization state whose field pattern can be expressed after make the simple math transformation of $E_x$ and $E_y$:

\[
E_x = E_R + E_L \\
E_y = E_R - E_L
\]

where:

\[
\varepsilon_x = \alpha_x E_x \cos(\omega t + \pi/2) \\
\varepsilon_y = \alpha_y E_y \cos(\omega t)
\]

thus the electric field pattern can be calculated as:

\[
\left(\frac{\varepsilon_x}{E_R + E_L}\right)^2 + \left(\frac{\varepsilon_y}{E_R - E_L}\right)^2 = 1
\]

The above is a elliptical polarization which can be seen as the superposition of two circular polarization possessing different magnitude and direction. And the general elliptical polarization pattern is shown below:
Questions

1. What is the polarization of the natural light and why?

2. What's the relationship between these polarization and how can we control?

3. How can we define the rotation direction of elliptical polarization?

Answers

1. What is the polarization of the natural light and why?

The cause of the light polarization is the vibration direction of the lighting material. The natural light comes from the molecular vibration of the nuclear fusion in Sun and this vibration is homogeneous on all directions. Thus the natural light does not have a specific polarization or can be defined as non-polarized EMW.

2. What's the relationship between these polarization and how can we control?

The circular polarization can be seen as the superposition of two linear polarization waves having the same magnitude, orthogonal polarization direction and \( \pi/2 \) phase difference. The elliptical polarization wave can be seen as the superposition of two linear polarization waves having the different magnitude, orthogonal polarization state and the stable phase difference. Above all, the linear polarization state and circular polarization state are only the special states of elliptical polarization state.

3. How can we define the rotation direction of elliptical polarization?

the circular and elliptical polarization state can be formed by letting linear polarization wave pass through a quarter wave plate at the specific angle. And the linear polarization state can be formed by the linear polarization plate as well as the polarization rotator.
